Objetivo final

Slide 7

- Segmentação do defeito
 - Substituir operador humano

- Alguns sinais só podem ser observados módulo 2π , e isso também pode se aplicar a imagens bidimensionais e tridimensionais. Nesses casos, o desempacotamento de fase é necessário para recuperar o sinal subjacente desempacotado.
- Foram selecionadas 43 imagem com o padrão de franja borboleta, resultado da medição da tubulação para o estudo.

desempacotamento

Threshold

Operador humano

- **Segmentação Semântica - UNET** - usa um modelo de rede totalmente convolucional para a tarefa.
- **Dados** – Imagens (43) e suas máscaras correspondentes (43), na qual, 38 imagens foram para treino 5 imagens foram para teste.

U-Net para segmentação semântica

- **Segmentação Semântica - UNET** - usa um modelo de rede totalmente convolucional para a tarefa.

- A segmentação pelo método de visão clássica das imagens de padrões borboletas foram satisfatória quando comparada com a segmentação feita pelo operador humano.
 - Para avaliação do método foi calculado o parâmetro IoU (interseção sobre a união) chegando a um valor de 0.75
- A segmentação semântica (U-Net), caracterizou o padrão borboleta com um retângulo para todas as imagens.
 - O baixo número de exemplares para treino pode ter comprometido a eficácia do método.
 - Outro fator foi a necessidade de diminuir a dimensão das imagens originais (2048x2048) para 256x256 com intuito de agilizar o treinamento, visto que com a dimensão original levava muito tempo para processamento. E dessa forma algumas informações importantes para a rede podem ter se perdido.
 - Para avaliação do método foi calculado o parâmetro IoU (interseção sobre a união) chegando a um valor de 0.27

Obrigada
